# Migration, migrant integration and support for social spending: The case of Switzerland - Online Appendix

Dennis Spies and Alexander Schmidt-Catran - University of Cologne, Germany

Figure OA1: Robustness check – model with socio-demographic controls

Notes: * p < .05, ** p<.01, *** p<.001 (two-sided tests), unweighted data, cluster-adjusted robust standard errors. All individual-level variables are controlled for age, gender and equivalized household income. The paths are not shown for reasons of graphical presentation. Solid boxes indicate individual-level variables, while dashed boxed indicate canton-level variables. Black paths are significant and display the (unstandardized) coefficients and their significance-levels. Grey paths are not significant. In this full model, the measurement model for cultural threat includes error correlations between three variables (Culture Composed, Culture Enriched, Traditions/Values).
